ABSTRACT

This study presents the bio-guided chemical investigation of a 80% methanol extract of *Hippocrepis emerus* flowers, a perennial non-climbing shrub. Liquid-liquid partitioning in solvents of increasing polarity combined to biological screening enabled to determine the EtOAc and *n*-BuOH soluble fractions as the most active parts of the extract. These fractions were chemically profiled by using a ^{13}C NMR-based dereplication method, resulting in the identification of twenty-six compounds. The dereplication process was completed by purification of some unknown or minor compounds of the *n*-BuOH fraction. Three new glycosylated flavonoids, namely kaempferol-3-*O*- β -D-glucopyranosyl-7-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)- α -L-rhamnopyranoside (**1**), isorhamnetin-3-*O*- β -D-glucopyranosyl-7-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)- α -L-rhamnopyranoside (**2**) and quercetin-3-*O*- β -D-glucopyranosyl-7,4'-*O*- α -L-dirhamnopyranoside (**3**), together with twelve known compounds (**4** – **15**) were isolated. Their structures were elucidated by spectroscopic methods including NMR, HR-ESI-MS and UV. The antioxidant activity of fractions and isolated compounds were evaluated using DPPH and hydroxyl radical scavenging and CUPRAC assays. In parallel, their inhibitory properties against mushroom tyrosinase and human neutrophil elastase enzymes were assessed. Three quercetin glycosides exhibited a significant radical-scavenging activity and two flavonoids showed a moderate elastase inhibitory activity.

Keywords

Flavonoid; dereplication; *Hippocrepis emerus*; antioxidant; tyrosinase; elastase.

1. Introduction

Skin aging is a complex biological process influenced by oxidative stress and leading to matrix remodeling associated with hyperpigmentation phenomena. Prevention of these dynamic processes is a major issue for the dermo-cosmetics sector and substantial research efforts are being made to discover new protective ingredients (Parvez et al., 2007, Pandel et al., 2013, Kanlayavattanakul et al., 2018). Plants contain a wide range of secondary metabolites, which are commonly used as active molecules in pharmaceuticals or herbal cosmetics (Xu et al., 2009, Abdul Karim et al., 2014, Srinivas et al., 2015, Fierascu et al., 2018, Mukherjee et al., 2011). Plant extracts can contain high concentration of phenolic compounds (phenolic acids, flavonoids, anthocyanidins) that act as strong *H*-donors, reducing agents or oxygen quenchers, retarding the aging process. The antioxidant potency of these phenolic compounds can be easily determined by biochemical tests such as DPPH assay, the ferric reducing/antioxidant power (FRAP) assay, the ABTS assay or the cupric ion reducing antioxidant capacity (CUPRAC) assay (Fierascu et al., 2018). Flavonoids and other phenolics have also been reported as potent whitening agents due to their tyrosinase inhibitory activity (Parvez et al., 2007, Kanlayavattanakul et al., 2018) and some of them could play a role in matrix remodeling *via* an elastase inhibitory effect (Xu et al., 2009). For example, kaempferol and quercetin are flavonols showing skin healing effect (Mukherjee et al., 2011, Sharafzadeh et al., 2013) and consequently, various topical delivery systems of flavonoids have been studied (Nagula and Wairkar, 2019).

The papilionaceous corolla and leaves of Fabaceae species are a rich source of flavonoids and phenolic compounds. The genus *Hippocrepis* from the Fabaceae family comprises about twenty species, mostly occurring in the Mediterranean regions. The typical papilionaceous flowers are grouped into umbels or axillaries at the head of twigs, most often bright yellow and fragrant. Chemical investigations of the genus *Hippocrepis* have revealed the presence of flavonoids (Sherwood et al., 1973, Harborne, 1981, Al-Snafi, 2016), sterols (Komissarenko and Kovalev, 1988), coumarins (Piovan et al. 1996, Al-Snafi, 2016), cardiotonic glycosides, saponins (Al-Snafi, 2016), and sugars (Moyer et al., 1977). *Hippocrepis* species are traditionally used for their diuretic, purgative and heart-stimulating properties, but their dermo-cosmetic activities, including antioxidant properties, have not yet been studied.

Hippocrepis emerus (L.) Lassen (= *Coronilla emerus* L.) is a perennial non-climbing shrub species belonging to the subfamily Faboideae, tribe Loteae (Heywood and Ball, 1968,

Lassen, 1989, Huang, 1998). It is quite common on the margins and in the gaps of broad-leaved forests and in the supramediterranean maquis (Central and Southern Europe). In France, *Hippocrepis emerus* is a common species in the Mediterranean region, extending towards the west in the middle basin of the Garonne and in the Pyrenees (Lombard and Arnal, 2018). It is generally absent from highly disturbed ecosystems or markedly dry environments (Aronne et al., 2011). Some flavonoids have been isolated from the leaves and flowers of *H. emerus* (Harborne and Boardley, 1983), as well as furan derivatives phytoalexins after fungus inoculation (Dewick and Ingham, 1980), and saponins (Marquina and Figueras, 1952).

In this work, the chemical profile of *H. emerus* flowers was investigated using a ^{13}C NMR-based dereplication methodology combined to a bio-guided fractionation and purification procedure with a focus on phenolic compounds. The antioxidant, tyrosinase and elastase inhibitory activities of the crude MeOH extract, fractions and isolated compounds were evaluated.

2. Results and discussion

2.1. Preliminary bio-guided evaluation of crude extract and fractions of *H. emerus* flowers

A 80% MeOH extract (HEM) was obtained from *H. emerus* flowers and partitioned successively in solvents of increasing polarity, resulting in a dichloromethane fraction (DCMF), ethyl acetate fraction (EAF) and *n*-butanol fraction (*n*-BF). The antioxidant potential of HEM and its fractions was estimated by three chemical assays, including the DPPH and hydroxyl radical assays to measure the ability to scavenge free radicals and the CUPRAC assay to evaluate their cupric reducing capacity. Their ability to inhibit mushroom tyrosinase and human neutrophil elastase activity was also tested. The results are shown in Table S1. For EAF and *n*-BF, a substantial cupric ion reducing capacity was observed (IC_{50} 2.8 $\mu\text{g/mL}$ and 3.8 $\mu\text{g/mL}$, respectively), as well as moderate DPPH (IC_{50} 71.7 $\mu\text{g/mL}$ and 127.2 $\mu\text{g/mL}$, respectively) and hydroxyl radicals scavenging activities (IC_{50} 239.3 $\mu\text{g/mL}$ and 139.5 $\mu\text{g/mL}$, respectively). A moderate tyrosinase inhibitory activity was also observed for EAF and *n*-BF (IC_{50} 212.0 $\mu\text{g/mL}$ and 147.5 $\mu\text{g/mL}$, respectively). Concerning the elastase inhibitory activity, HEM, DCMF, EAF and *n*-BF showed less than 5% inhibition at 10 $\mu\text{g/mL}$. The EAF and *n*-BF showing the most interesting biological activities were chemically investigated through a bioassay-guided isolation strategy in order to tentatively determine the active constituents.

2.2. Chemical profiling of the EtOAc fraction (EAF)

The major compounds of EAF were identified using a dereplication method combining Centrifugal Partition Chromatography (CPC) with NMR analyses and pattern recognition of metabolite spectral fingerprints, without purification of individual components (Hubert et al., 2014). The CPC fractionation of EAF was performed with the biphasic solvent system MtBE/CH₃CN/water (3/3/4, v/v/v) which was selected to recover moderately polar compounds. As a result, 23 CPC sub-fractions (EAF₁₋₂₃) containing simplified mixtures or even pure compounds were obtained. After ¹³C NMR analyses of EAF₁₋₂₃, all spectra of the fraction series were processed and submitted to Hierarchical Clustering Analysis (HCA) for the recognition of ¹³C NMR metabolite fingerprints. In this way, similarity measurements between ¹³C NMR signals belonging to individual structures within the fraction series were visualized as “chemical shift clusters” on a HCA correlation heat map given in Fig. 1. As a result, 16 major chemical shift clusters colored in yellow were revealed on the heat map, corresponding to the major metabolites of the EAF (Fig. 1).

With the help of an in-house database containing predicted chemical shift values of natural metabolites, the correlated chemical shifts of cluster 1 in fractions EAF₂₁₋₂₂ were assigned to pinitol. The identification of pinitol was easily confirmed by checking HSQC, HMBC and COSY data of fraction EAF₂₁ and by comparison with literature data (Deans et al., 2018). By means of the same database search strategy, clusters 2 to 13 were identified as: *p*-hydroxybenzoic acid (Lee et al., 2012) and *Z/E*-*p*-coumaric acid (Torres-Naranjo et al., 2016) (cluster 2; fractions EAF₄₋₆), a mixture of suberic acid and 3-nitropropionic acid (cluster 3; fractions EAF₄₋₆), kaempferol-7-*O*- α -L-rhamnopyranoside (**11**) (Ozden et al., 1998) (cluster 4; fractions EAF₇₋₉), methyl benzoate and salicylic acid (cluster 5; fraction EAF₃), oleic acid (Purcell et al., 1966) (cluster 6; fractions EAF₁₋₂), rhamnocitrin-3-*O*- β -D-glucopyranoside (Bicha et al., 2016, Hu et al., 2017) (clusters 7 and 7', fraction EAF₁₁), rhamnocitrin-3,4'-*O*- β -D-diglucopyranoside (Cui et al., 1993, Bicha et al., 2016) (clusters 8, 8' and 8''; fractions EAF₁₈₋₁₉), saccharose (Deans et al., 2018) (cluster 9; fractions EAF₂₁₋₂₂), a mixture of kaempferol-3-*O*- β -D-glucopyranoside (Xiao et al., 2006) and three 3-nitropropanoyl- β -D-glucopyranoses (corollin, coronillin and coronarian) (Moyer et al., 1977) (cluster 10; fraction EAF₁₂), kaempferol (Xiao et al., 2006) (cluster 11; fractions EAF₃₋₄), kaempferol-3-*O*- β -D-glucopyranosyl-7-*O*- α -L-rhamnopyranoside (**5**) (Ozden et al., 1998) (cluster 12; fraction EAF₁₇), and protocatechuic acid (Lee et al., 2012) (cluster 13; fraction EAF₈).

Among the compounds elucidated by dereplication, pinitol, *p*-hydroxybenzoic acid, suberic acid, kaempferol-7-*O*- α -L-rhamnopyranoside, rhamnocitrin-3-*O*- β -D-glucopyranoside, rhamnocitrin-3,4'-*O*- β -D-diglucopyranoside and protocathechuic acid are reported here for the first time in the genus *Hippocrepis*. Three were previously isolated from *H. emerus* (methyl benzoate, kaempferol-3-*O*- β -D-glucopyranoside and kaempferol-3-*O*- β -D-glucopyranosyl-7-*O*- α -L-rhamnopyranoside) (Harborne and Boardley, 1983, Joulain, 1983) and the seven other compounds were already known in the genus *Hippocrepis* (Joo et al., 1975, Moyer et al., 1977, Kovalev and Komissarenko, 1983, Kovac et al., 1986, Opletal and Sovovo, 1986, Guerrero et al., 2017).

2.3. Chemical profiling of *n*-BuOH fraction (*n*-BF)

The *n*-BF was composed of a very complex mixture of more polar metabolites as compared to the EAF. Therefore, five fractions (*n*-BFA – *n*-BFE) were firstly produced from the *n*-BF on a Diaion HP-20 column in order to simplify its chemical composition and then evaluated for their biological activities. The results showed that *n*-BFD exhibited the best DPPH radical scavenging activity (IC₅₀ 87.7 μ g/mL), whereas *n*-BFC and *n*-BFD showed a good hydroxyl radical scavenging activity (IC₅₀ 130.7 μ g/mL and 121.7 μ g/mL, respectively) and a significant cupric ion reducing power (IC₅₀ 2.3 μ g/mL and 1.9 μ g/mL, respectively) (Table S1). For the tyrosinase inhibitory activity, *n*-BFC exhibited the best result (IC₅₀ 130.5 μ g/mL). The elastase inhibition of *n*-BFA – *n*-BFE oscillates between 20 and 28% at the dose 10 μ g/mL. Comparing the activity of the *n*-BF with that of fractions *n*-BFA – *n*-BFE, we observed for *n*-BFD a substantial increase of DPPH and hydroxyl radicals scavenging activities and a higher cupric ion reducing power (Table S1). Thus, *n*-BFD was further chemically profiled by dereplication with the same NMR-based strategy as described for the EAF. As a result, 13 CPC sub-fractions (*n*-BFD₁₋₁₃) containing simplified mixtures or even pure compounds were obtained. The resulting HCA heat map containing correlated ¹³C NMR signals is also given in Fig. 1 and 10 major chemical shift clusters were revealed. The chemical shift values of clusters were assigned to *p*-hydroxybenzoic acid (clusters 2 and 2'; *n*-BFD₂), compound **5** (cluster 12), kaempferol-3-*O*- β -D-glucopyranosyl-7,4'-*O*- α -L-dirhamnopyranoside (**4**) (Harborne and Boardley, 1983) (clusters 14 and 14'; fraction *n*-BFD₁₂), a mixture of kaempferol-3-*O*- β -D-apiofuranoside (Williams et al., 2019), quercetin-3-*O*- β -D-apiofuranoside (Williams et al., 2019) and quercetin-3-*O*- β -D-glucopyranosyl-7-*O*- α -L-rhamnopyranoside (**6**) (Aboushoer et al., 2010) (cluster 15; fractions *n*-BFD₆₋₁₀), benzyl- β -D-

glucopyranoside (**13**) (Fujita et al., 1994) (clusters 16 and 16'; fraction *n*-BFD₆), and phenylethyl-β-D-glucopyranoside (**14**) (Bock and Pedersen, 1983) and (Z)-3-hexenyl-β-D-glucopyranoside (**15**) (Lee et al., 2012) (cluster 18; fraction *n*-BFD₄₋₆). For the fraction *n*-BFD₁₂, the database proposed an isorhamnetin tri-glycosylated, which could not be identified unambiguously (cluster 17).

Among the compounds elucidated by dereplication, quercetin-3-*O*-β-D-glucopyranosyl-7-*O*-α-L-rhamnopyranoside, kaempferol-3-*O*-β-D-glucopyranosyl-7-*O*-α-L-rhamnopyranoside and kaempferol-3-*O*-β-D-glucopyranosyl-7,4'-*O*-α-L-dirhamnopyranoside were previously identified in *H. emerus* (Harborne and Boardley, 1983) and the six other were unknown in the genus *Hippocrepis*. The structure of the tri-substituted flavonoid **4** was hypothetically proposed in *H. emerus* flowers by Harborne and Boardley, 1983) based on UV analysis and acid hydrolysis without confirming the structural assignments by NMR and MS data.

As summarized in Table S1, *n*-BFD exhibited the highest antioxidant activity. In addition, *n*-BFD contains six glycosides previously undescribed in the genus *Hippocrepis*. Thus, fractions *n*-BFD₆ to *n*-BFD₁₂, were further screened for their biological activity. As shown in Table S1, fractions *n*-BFD₆ to *n*-BFD₉ had the best antioxidant and anti-elastase activities. The screening results indicate that the fractionation of *n*-BFD has increased the DPPH radical scavenging potential and the elastase inhibitory activity.

2.4. Purification of the active fractions of *n*-BFD

Since active fractions *n*-BFD₆₋₉ contained metabolites which were not unambiguously identified over the dereplication process, further purifications were performed using semi-preparative and preparative HPLC. Fraction *n*-BFD₁₂ was also purified by semi-preparative HPLC because it contains a non-identified tri-glycosylated flavonoid. All purified chemical structures were unambiguously assigned based on NMR and HR-ESI-MS data which afforded three undescribed glycosylated flavonoids (**1** – **3**) and twelve known compounds (**4** – **15**).

Compound **1** was obtained as yellowish-brown solid with a molecular formula of C₃₃H₄₀O₂₀, deduced from its positive HR-ESI-MS analysis (*m/z* 779.2020, [M + Na]⁺). The UV spectrum showed the characteristic absorption of a flavonol skeleton at 210, 266 and 348 nm. The ¹H and ¹³C NMR spectra of **1** comprised resonances corresponding to aromatic and glycosidic protons and carbons. The ¹H NMR spectrum of **1** (Table 2) showed two doublets at δ_H 6.52 and 6.81 (each H, d, *J* = 2.1 Hz), due to H-6 and H-8 in A-ring, as well as. two

doublets at δ_{H} 8.11 and 6.92 (each 2H, d, $J = 8.9$ Hz), due respectively to the protons H-2', 6' and H-3', 5' of a 4'-hydroxyphenyl moiety in B-ring. These protons were correlated in the HSQC spectrum with their aromatic carbon atoms at δ_{C} 99.2, 94.2, 130.9, and 114.7, respectively. Complete assignment of the remaining resonances of the aglycone in the ^{13}C NMR spectrum of **1** was achieved by analysis of the HSQC and HMBC data which confirmed the presence of kaempferol (3,5,7,4'-tetrahydroxy-flavone) (Xiao et al., 2006). A full list of the corresponding assignments is given in Table 2. Furthermore, three anomeric proton resonances corresponding to *O*-linked sugars were observed in the ^1H NMR spectrum as three doublets at δ_{H} 5.37 ($J = 7.3$ Hz, H-1''), 5.62 ($J = 1.5$ Hz, H-1''') and 4.64 ($J = 7.7$ Hz, H-1'''). The signals of their corresponding ^{13}C NMR carbons were at δ_{C} 102.1 (C-1''), 98.1 (C-1''') and 104.5 (C-1'''), respectively. A methyl signal at δ_{H} 1.29 (d, $J = 5.4$ Hz, H-6'') and δ_{C} 16.8 indicated a 6-desoxy-hexose, whereas signals for two hydroxymethylenes [δ_{H} 3.54, dd, $J = 12.0, 5.7$ Hz, /3.73, dd, $J = 12.0, 2.3$ Hz (H-6''); δ_{C} 61.2 (C-6'') and δ_{H} 3.75, dd, $J = 12.0, 4.7$ Hz/3.88, dd, $J = 12.0, 1.5$ Hz (H-6'''); 60.8 (C-6''')] indicated two hexose moieties. Analysis of COSY correlations allowed us to assign complete spin systems of two β -D-glucopyranoses and an α -L-rhamnopyranose (Ozden et al., 1998, Bock and Pedersen, 1983) (Table 2). The ^{13}C NMR data of each monosaccharide were attributed by analysis of HSQC spectra and indicated the presence of two terminal β -D-glucopyranoses and a 3-substitued α -L-rhamnopyranose ($\delta_{\text{C-3'''}}$ 81.1). The relatively large $^3J_{\text{H-1,H-2}}$ values of the glucoses (7.3-7.7 Hz) indicated a β anomeric orientation for both glucopyranose units. The α -configuration of rhamnose deduced from the small $^3J_{\text{H-1,H-2}}$ value, was confirmed by the chemical shift of C-5 (δ_{C} 69.5) (Chang et al., 2007). The linkage sites of the monosaccharide units were determined by analysis of HMBC spectrum. The HMBC correlations between H-1'' (δ_{H} 5.37)/C-3 of the aglycone (δ_{C} 134.2) and H-1''' (δ_{H} 5.62)/C-7 of the aglycone (δ_{C} 161.9) indicated positions of sugars on the kaempferol, whereas correlation between H-1'''' (δ_{H} 4.64) and C-3''' ($\delta_{\text{C-3'''}}$ 81.1) indicated that the second glucose unit was linked to C-3''' of the rhamnose unit. Therefore, the structure of **1** was elucidated as kaempferol-3-*O*- β -D-glucopyranosyl-7-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)- α -L-rhamnopyranoside shown in Fig. 2.

Compound **2** was obtained as yellowish-brown solid with a molecular formula of $\text{C}_{34}\text{H}_{42}\text{O}_{21}$, deduced from the positive HR-ESI-MS analysis (m/z 809.2108, $[\text{M} + \text{Na}]^+$) and indicating an additional methoxy group by comparison with **1**. The UV spectrum showed the characteristic absorption of flavonol at 204, 254 and 354 nm. The ^1H and ^{13}C NMR spectra of **2** comprised resonances corresponding to aromatic and glycosidic protons and carbons, and

one methoxy group. The A-ring of the flavonol was represented by two *meta*-coupled resonances at δ_{H} 6.52 (d, $J = 2.0$ Hz; δ_{C} 99.3) and 6.81 (d, $J = 2.0$ Hz; δ_{C} 94.2), assigned to H-6 and H-8, respectively. In the COSY and ^1H NMR spectra, a three protons ABX system was present at δ_{H} 7.97 (d, $J = 1.7$ Hz, H-2'), 6.94 (d, $J = 8.5$ Hz, H-5') and 7.65 (dd, $J = 8.5, 1.7$ Hz, H-6'), typical of a 3',4'-disubstituted B-ring of a flavonoid nucleus. The location of the methoxy group was established at C-3' from the correlation observed in the HMBC spectrum from δ_{H} 3.97 (3H, s; δ_{C} 55.4) to C-3' (δ_{C} 147.1). Complete assignment of the remaining resonances of the aglycone in the ^{13}C NMR spectrum of **2** was achieved by analysis of the HSQC and HMBC data, which confirmed the presence of isorhamnetin (3,5,7,4'-tetrahydroxy-3'-methoxyflavone) (Roesch et al., 2004). A full list of the corresponding assignments is given in Table 2. Analysis of 2D NMR experiments of **2** and comparison of its ^1H and ^{13}C NMR data with those of **1** showed that **2** contained also three sugar units, two of them were elucidated as above as β -D-glucopyranoses and one was identified as a terminal α -L-rhamnopyranose (Ozden et al., 1998) (Table 2). The site of glycosylations was established at the 3 and 7 position of isorhamnetin, as demonstrated by the HMBC spectrum showing correlations from H-1''' (δ_{H} 5.63)/C-7 (δ_{C} 162.0), H-1'' (δ_{H} 5.51)/C-3 (δ_{C} 134.2) and H-1'''' (δ_{H} 4.64)/C-3''' (δ_{C} 81.1). Thus, the structure of compound **2** was concluded to be isorhamnetin-3-O- β -D-glucopyranosyl-7-O- β -D-glucopyranosyl-(1 \rightarrow 3)- α -L-rhamnopyranoside (Fig. 2).

Compound **3** was obtained as yellowish-brown solid. Its positive HR-ESI-MS spectra showed a pseudomolecular ion $[\text{M} + \text{Na}]^+$ at m/z 779.2007, indicating a molecular formula of $\text{C}_{33}\text{H}_{40}\text{O}_{20}$. The UV spectrum showed the characteristic absorption of flavonol at 208, 256 and 348 nm. The ^1H and ^{13}C NMR spectroscopic data of compound **3** showed two distinct parts, the aglycone and three sugars. The ^1H and ^{13}C NMR spectra showed characteristic signals of quercetin (3,5,7,3',4'-pentahydroxy-flavone) at δ_{H} 6.46 (d, $J = 2.1$ Hz, H-6; δ_{C} 99.9), 6.82 (d, $J = 2.1$ Hz, H-8; δ_{C} 94.8), 7.67 (d, $J = 2.1$ Hz, H-2'; δ_{C} 117.2), 7.18 (d, $J = 9.3$ Hz, H-5'; δ_{C} 116.7) and 7.67 (dd, $J = 9.1, 2.2$ Hz, H-6'; δ_{C} 121.6) (Ibrahim et al., 2016) (Table 2). The ^1H and ^{13}C NMR spectra showed three anomeric signals at δ_{H} 5.51 (d, $J = 7.1$ Hz, H-1''; δ_{C} 101.2), 5.57 (d, $J = 1.4$ Hz, H-1'''; δ_{C} 98.9) and 5.43 (d, $J = 1.4$ Hz, H-1''''; δ_{C} 99.6), in addition to two methyl signals (δ_{H} 1.13, 6H, d, $J = 6.1$ Hz, H-6''' and H-6''''; δ_{C} 18.4). The analysis of COSY, HSQC and HMBC experiments led to the identification of three terminal sugar units: two α -L-rhamnopyranoses and one β -D-glucopyranose (Ozden et al., 1998) (Table 2). The HMBC correlations between H-1''/C-3 (δ_{C} 134.6), H-1'''/C-7 (δ_{C} 162.2), and H-1''''/C-

4' (δ_C 147.1) indicated the glycosylation sites. Therefore, the structure of **3** was elucidated as quercetin-3-*O*- β -D-glucopyranosyl-7,4'-di-*O*- α -L-rhamnopyranoside (Fig. 2).

Compounds **4-6**, **11**, and **13-15** already identified during the dereplication process were also isolated in addition to isorhamnetin-3-*O*- β -D-glucopyranosyl-7-*O*- α -L-rhamnopyranoside (**7**) (Roesch et al., 2004), kaempferol-3-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 6)- β -D-glucopyranoside (**8**) (Kazuma et al., 2003), quercetin-3-*O*- α -L-rhamnopyranosyl-(1 \rightarrow 6)- β -D-glucopyranoside (**9**) (Ibrahim et al., 2016), quercetin (**10**) (Ibrahim et al., 2016), and quercetin-7-*O*- α -L-rhamnopyranoside (**12**) (Ibrahim et al., 2016) (Fig. 2 and S2). The structural assignments of these compounds were made by ESI-MS, 1D and 2D-NMR analysis.

2.5. Biological assays on compounds

Isolated compounds were evaluated for their antioxidant potential using DPPH and hydroxyl radicals scavenging assays, CUPRAC assay, and for their tyrosinase and elastase inhibitory properties. Some compounds have not been screened for these five assays due to poor yields. For these compounds, their biological potential was discussed based on literature data when possible. As summarized in Table 1, compounds **6**, **9** and **12** exhibited the best antioxidant activities. Compounds **6** and **9** (Arimboor et al., 2012) exhibited the highest antioxidant potential in DPPH, hydroxyl radicals scavenging, and CUPRAC tests (**6**: IC₅₀ 44.4, 31.1 and 23.3 μ M, respectively; **9**: IC₅₀ 28.8, 145.8 and 13.9 μ M, respectively). Compound **12** exhibited also good activities in DPPH and CUPRAC tests (IC₅₀ 81.2 and 14.5 μ M, respectively). Compound **5** showed moderate activities in hydroxyl scavenging and CUPRAC assays (IC₅₀ 110.2 and 47.9 μ M, respectively) and compound **11** (Zhou et al., 2015) exhibited moderate activities in DPPH and CUPRAC tests (IC₅₀ 83 and 72.8 μ M, respectively). Compound **8** showed moderate activity only in CUPRAC assay (IC₅₀ 57.7 μ M), whereas compounds **1-4**, **7** and **13** (Kiem et al., 2012) exhibited low antioxidant activities. The kaempferol glycosides **5**, **8** and **11** were more active in CUPRAC assay than the isorhamnetin glycosides **2** and **7**. In most cases, quercetin derivatives exhibited higher antioxidant activity than kaempferol and isorhamnetin due to the presence of two free OH group at positions 3' and 4' of the B-ring (Prochazkova et al., 2011). Our results confirm this relationship since the most active compounds **6**, **9** and **12** are quercetin-type flavonoids. Moreover, the results indicated also that compounds **5** and **6** (having two sugars in positions 3 and 7 of the aglycone) showed better activity in antioxidant assays when compared to compounds **3** and **4**

(having three sugars in positions 3, 7 and 4' of the aglycone), due to glycosylation at 4' position in **3** and **4**.

Concerning the anti-tyrosinase tests, only compound **14** (phenylethylglucoside) (Luyen et al., 2017) exhibited a significant activity (IC_{50} 63.4 μ M). It is more active than its analog compound **13** (benzylglucoside). This suggested another structure-activity relationship based on chain length that would increase anti-tyrosinase activity. Only compound **8** showed a moderate elastase inhibitory activity (IC_{50} 86.1 μ M). The inhibitory capacity of compounds **8** and **12** is greater than that of compound **9** and **11**, respectively, but lower than that of quercetin (**10**) found in the literature (Sartor et al., 2002). These results suggest that sugars attached to positions 3 or 7 of the aglycone decrease anti-elastase activity.

3. Conclusions

Thirty-two secondary metabolites including flavonoids, phenolic acids, coronillins and glycosides derivatives, were identified in a flower extract of *Hippocrepis emerus*. Three new flavonoids were identified, and seventeen compounds are reported here for the first time in the genus *Hippocrepis*. ^{13}C NMR-based dereplication combined to bioactivity-guided fractionation allowed to rapidly determine the global chemical composition of the extract and to orientate purification and biological screening of the most interesting fractions.

On a chemical standpoint, the originality in structures of the characterized flavonoids lies in different position of the osidic part. The tri-substituted flavonoids **3** and **4** are characteristic of this species. Compound **4** has been previously mentioned in *H. emerus* flowers on the base of UV analysis and acid hydrolysis (Harborne and Boardley, 1983). This study confirms the presence of **4** in this species and complete and unambiguous 1H and ^{13}C NMR chemical shift assignments for this compound have been established by means of 1D- and 2D-NMR spectroscopic experiments (Table 2). Among the identified compounds, quercetin-type flavonoids **6**, **9** and **12** showed a powerful antioxidant activity and phenylethyl- β -D-glucopyranoside (**14**) showed a mushroom tyrosinase inhibition. These tests have highlighted the antioxidant activity of glycosylated flavonoids and more particularly quercetin-type flavonoids with two maximum sugars. The EAF, *n*-BF and the bi-glycosylated flavonoids of quercetin type identified from *H. emerus* could be valued in the dermo-cosmetic field for their very interesting antioxidant activities.

4. Experimental

4.1. General experimental procedures

Optical rotations of pure compounds were measured in CH₃OH using a Perkin-Elmer 341 Polarimeter (589 nm, 20 °C). ¹H-, ¹³C-NMR and 2D-NMR measurements were recorded at 298 K in CH₃OH-*d*₄ or DMSO-*d*₆ on a Bruker Avance AVIII-600 spectrometer (Karlsruhe, Germany) (¹H at 600 MHz and ¹³C at 150 MHz) equipped with a 5 mm TCI cryoprobe. 2D-NMR experiments were performed using standard Bruker microprograms (TopSpin 3.2 software). HR-ESI-MS experiments were realized using a Micromass Q-TOF micro instrument (Manchester, UK). Mass spectra were recorded in the positive-ion mode in the range *m/z* 100–2000, with a mass resolution of 20 000 and an acceleration voltage of 0.7 kV. Preparative HPLC was performed on Armen Instrument apparatus equipped with an AP 250 pump and a Knauer (Merck) detector UV K-2501. Semi-preparative HPLC was realized on a Dionex apparatus equipped with an ASI-100 automated sample injector, a STH 585 column oven, a P580 pump, a diode array detector UVD 340S and the Chromeleon[®] software version 6.8. Analytical HPLC experiments were performed using a ThermoFisher Ultimate 3000 (Thermo Fischer Scientific, Villebon sur Yvette, France), equipped with a 4 ways pump LPG 3400 SD, an automatic injector WPS 3000 SL, a UV/visible diode array detector 3000 and the Chromeleon[®] software version 6.8. A manually packed C₁₈column (LiChrospher, 20 x 5 cm, 12 μ) was used for preparative HPLC. The mobile phase consisted of H₂O with TFA (0.0025%) and CH₃CN with a flow rate of 100 mL/min and the chromatograms were monitored at 205, 254, 300 and 360 nm. A prepacked C₁₈ column (Phenomenex Luna, 250 × 15 mm, 5 μ) was exploited for semi-preparative HPLC. The mobile phase was composed of H₂O with TFA (0.0025%) and CH₃CN with a flow rate of 6 mL/min and the chromatograms were monitored at 205, 254, 300 and 360 nm. A prepacked C₁₈ column Uptisphere Strategy C₁₈ (Interchim, 4.6 × 250 mm, 5 μ) was used for analytical HPLC and the mobile phase consisted of H₂O with TFA (0.0025% v/v) and CH₃CN. A gradient elution method was applied from 5% to 80% of CH₃CN in 30 min with a flow rate of 1 mL/min and the chromatograms were monitored at 205, 254, 300 and 360 nm. CC was carried out on HP-20 resin (Sigma Aldrich). Thin-layer chromatography (TLC) was carried out on silica gel 60 F₂₅₄ pre-coated aluminum plates (0.2 mm, Merck), using the system CHCl₃/MeOH/H₂O (70/30/5, v/v/v) as the mobile phase. The spots were visualized under UV light (254 and 366 nm) using high-performance thin-layer chromatography (HPTLC, CAMAG TLC Visualizer 2) and sprayed with 50% H₂SO₄ followed by heating. A FLUOstar Omega spectrophotometer (BMG LABTECH) was used for measuring the absorbance of antioxidant and anti-tyrosinase

assays. An Infinite F200 PRO spectrofluorimeter (Tecan, Lyon, France) was used for measuring the fluorescence of anti-elastase assay.

4.2. Plant material

The flowers of *Hippocrepis emerus* (L.) Lassen (= *Coronilla emerus* L.) (Fabaceae) was collected in Cormontreuil (Northeastern of France: 49°21'67"N, 4°05'E) in April 2016, authenticated by Dr. Abdulmagid Alabdul Magid and dried at room temperature. A voucher specimen was deposited at the Herbarium of the Botanic laboratory-Faculty of Pharmacy, University of Reims Champagne-Ardenne, under the sheet reference (MA-HE-2016-04).

4.3. Extraction and isolation

The dried and powdered *H. emerus* flowers (300 g) was macerated in 80% MeOH (3 x 3 L, 24 h) at room temperature, followed by concentration at 40 °C under vacuum in order to evaporate the methanol and obtain an aqueous solution. An aliquot of the aqueous solution (100 mL) was evaporated to dryness to obtain the 80% MeOH extract (HEM) (2.9 g). The aqueous solution (1 L) was extracted successively with dichloromethane (3 x 750 mL), ethyl acetate (3 x 750 mL) and *n*-butanol (3 x 750 mL), then dried under reduced pressure to yield DCMF (2.8 g), EAF (2.4 g), and *n*-BF (11.4 g), respectively and a water-soluble part (6.9 g). The *n*-BF fraction was dissolved in 1 L H₂O and then subjected to a Diaion HP-20 macroporous resin column (5.5 x 26 cm), eluting sequentially with a mixture of MeOH-H₂O (0%, 25%, 50%, 75% and 100% MeOH, 1.8 L each) to provide five fractions *n*-BFA – *n*-BFE, respectively.

4.3.1. Centrifugal partition chromatography

Centrifugal partition chromatography (CPC) experiments were carried out using a lab-scale FCPE300® column of 303 mL capacity (Rousselet Robatel Kromaton, Annonay, France) containing 7 circular partition disks and engraved with a total of 231 partition twin-cells (≈ 1 mL per twin cell). The liquid phases were pumped by a KNAUER Preparative 1800 V7115 pump (Berlin, Germany). The column was coupled on-line with a UVD 170 S detector set at 210, 254, 280 and 366 nm (Dionex, Sunnyvale, CA, USA). Fractions of 20 mL were collected by a Pharmacia Superfrac collector (Uppsala, Sweden). The solvent system was MtBE/CH₃CN/water in the ratio 3/3/4 (v/v/v). The column rotation speed was set at 1200 rpm and the flow rate at 20 mL/min.

EAF and *n*-BFD were subjected independently to CPC; each one was dissolved in 25 mL of a mixture of both lower phase (20 mL) and upper phase (5 mL). For the separation of EAF (1.6 g injected), the upper phase of the biphasic solvent system was pumped for 100 min in the ascending mode. Then the column was extruded by pumping the organic phase in the descending mode still at 20 mL/min. Fractions of 20 mL were collected over the whole experiment. All fractions were analyzed by TLC and HPLC and then pooled, giving fractions EAF₁₋₂₃.

For the separation of *n*-BFD (1.45 g), the CPC method was identical, except for the pumping time of the upper phase which was 200 min. All fractions were analyzed by TLC and HPLC and then pooled, giving fractions *n*-BFD₁₋₁₃.

4.3.2. NMR analyses and dereplication of the metabolites

As a first step in this developed ¹³C NMR-based dereplication method ([Hubert et al., 2014](#)), structures and names of metabolites already described in the genus *Hippocrepis* (n=68) were collected from the reports available in the literature. The predicted ¹³C NMR chemical shifts of each one was then stored into a local database already comprising 2500 structures of natural compounds (NMR Workbook Suite 2012, ACD/Labs, Ontario, Canada). In the second step, all CPC fractions were dried under vacuum and an aliquot (up to 20 mg when possible) was dissolved in 600 µL of DMSO-*d*₆ and analyzed by ¹³C NMR. ¹³C NMR spectra were acquired at 150.91 MHz. A standard zgpg pulse sequence was used with an acquisition time of 0.9 s and a relaxation delay of 3 s. For each sample, 1024 scans were added to obtain a satisfactory signal-to-noise ratio. The spectral width was 240 ppm and the receiver gain was set to the highest possible value. Spectra were then manually phased, baseline corrected using the TOPSPIN3.2 software (Bruker), and calibrated on the central resonance of DMSO-*d*₆ (δ 39.8 ppm).

The last step consisted in the binning of all ¹³C NMR signals followed by the visualization of the whole dataset as a heat map. For this purpose, the absolute intensities of all ¹³C NMR signals detected in the spectra of the fraction series were automatically collected and each resulting peak list was stored as a text file. The binning step was performed by using a locally developed computer script written in Python language. Its principle was to divide the ¹³C spectral width (from 0 to 240 ppm) into regular chemical shift windows (Δδ = 0.2 ppm), and to associate the absolute intensity of each peak to the corresponding bin. The resulting table was imported into the PermutMatrix version 1.9.3 software (LIRMM,

Montpellier, France) and submitted to Hierarchical Clustering Analysis (HCA) for data visualization. Then the chemical shifts clusters regrouped with the HCA were compared to a database to identify the compounds. In order to confirm the structures of the identified compounds, additional 1D and 2D NMR experiments (^1H NMR, HSQC, HMBC, and ^1H - ^1H -COSY) were registered and analyzed.

4.3.3. HPLC purification of *n*-BFD

Fractions *n*-BFD₆₋₇ were subjected to preparative HPLC using the gradient system (15-25% CH₃CN, 45 min) to yield compounds **13** (t_R =7.7 min, 15 mg), **6** (t_R =8.4 min, 38 mg), **9** (t_R =12.8 min, 15 mg) and **8** (t_R =16.2 min, 36 mg). Subfraction 17 was purified by semi-prep. HPLC with isocratic system (17% CH₃CN, 20 min) to yield compound **5** (t_R =9.8 min, 8 mg), and a mixture of **14** and **15** (t_R =14.5 min, 4 mg). Subfraction 27-28 was purified by semi-prep. HPLC with gradient system (30-35% CH₃CN, 20 min) to yield compounds **12** (t_R =7.3 min, 4 mg), **11** (t_R =10.2 min, 7 mg), and **10** (t_R =12.4 min, 3 mg). Fractions *n*-BFD₈₋₉ were purified by semi-prep. HPLC with gradient system (17-22% CH₃CN, 15 min) to yield compound **7** (t_R =9.0 min, 12 mg). Fraction *n*-BFD₁₂ was purified by preparative HPLC with gradient system (17-23% CH₃CN, 45 min) to yield compounds **3** (t_R =5.5 min, 20 mg) and **4**: (t_R =6.5 min, 55 mg). Subfraction 33-35 was purified by semi-prep. HPLC with isocratic system (17% CH₃CN, 20 min) to yield compounds **1** (t_R =11.2 min, 0.6 mg) and **2** (t_R =11.9 min, 2 mg).

4.4. Kaempferol-3-*O*- β -D-glucopyranosyl-7-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)- α -L-rhamnopyranoside (**1**)

Yellowish-brown solid; $[\alpha]_D$ -8.8 (c 0.05, MeOH); UV (MeOH) λ_{\max} (log ϵ) 210 (4.22), 266 (4.03) and 348 (3.93); ^1H and ^{13}C NMR data, see Table 2; HR-ESI-MS (positive-ion mode) m/z : 779.2020 $[\text{M} + \text{Na}]^+$ (calculated for C₃₃H₄₀O₂₀Na, 779.2011).

4.5. Isorhamnetin-3-*O*- β -D-glucopyranosyl-7-*O*- β -D-glucopyranosyl-(1 \rightarrow 3)- α -L-rhamnopyranoside (**2**)

Yellowish-brown solid; $[\alpha]_D$ -7.8 (c 0.06, MeOH); UV (MeOH) λ_{\max} (log ϵ) 204 (4.16), 254 (3.86) and 354 (3.74); ^1H and ^{13}C NMR data, see Table 2; HR-ESI-MS (positive-ion mode) m/z : 809.2108 $[\text{M} + \text{Na}]^+$ (calculated for C₃₄H₄₂O₂₁Na, 809.2116).

4.6. Quercetin-3-*O*- β -D-glucopyranosyl-7,4'-*di-O*- α -L-rhamnopyranoside (**3**)

Yellowish-brown solid; $[\alpha]_D$ -7.0 (c 0.58, MeOH); UV (MeOH) λ_{\max} ($\log \epsilon$) 208 (4.34), 256 (4.13) and 348 (4.01); ^1H and ^{13}C NMR data, see Table 2; HR-ESI-MS (positive-ion mode) m/z : 779.2007 $[\text{M} + \text{Na}]^+$ (calculated for $\text{C}_{33}\text{H}_{40}\text{O}_{20}\text{Na}$, 779.2011).

4.7. Antioxidant bioassay procedures

4.7.1. DPPH radical scavenging activity

Extracts, fractions and compounds **1-7**, **10**, **12** and **13** were tested for their DPPH radical scavenging activity. The free radical scavenging capacity was determined by using the stable 1,1-diphenyl-2-picrylhydrazyl (DPPH) free radical (Sientzoff et al., 2015). Briefly, 5 μL of different concentrations of the samples (dissolved in $\text{H}_2\text{O}/\text{DMSO}$ 9/1, v/v) were added to 95 μL of a DPPH solution (158 μM , dissolved in $\text{EtOH}/\text{H}_2\text{O}$ (1/1, v/v) freshly prepared. The reaction proceeded for 30 min at 37 °C on a 96-well microplate and the absorbance was then read at 515 nm. The DPPH inhibition percentage was calculated as followed: % inhibition $[(\text{Ab}_{\text{control}} - \text{Ab}_{\text{sample}})/\text{Ab}_{\text{control}}] \times 100$. A DPPH solution in EtOH 50% was used as a control. The curve of the % scavenging activity against the concentration of sample was prepared by MSExcel based program to obtain the IC_{50} . Samples were prepared at concentrations of 200, 100, 50, 25, 12.5 and 6.25 $\mu\text{g}/\text{mL}$. Ascorbic acid and quercetin were used as positive controls. All the tests were conducted in triplicate for each concentration examined.

4.7.2. Hydroxyl radical scavenging activity

Extracts, fractions and compounds **2**, **4-6**, **8**, **10**, **11** and **13** were tested for their hydroxyl radical scavenging activity. Hydroxyl radical scavenger ability was measured according to a literature procedure (Wang et al., 2007) with a few modifications. Hydroxyl radical was generated from Fenton reaction between 1.5 mM FeSO_4 and 6 mM H_2O_2 , (10:7, v/v) at 37 °C for 30 min before the assay and detected by their ability to hydroxylate salicylate. The reaction mixture (300 μL) contained 100 μL FeSO_4 (1.5 mM), 70 μL H_2O_2 (6 mM, freshly prepared, 30 μL sodium salicylate (20 mM) and 100 μL of varying concentrations of samples (1330, 665, 332.5, 166.25, 83.12 and 41.56 $\mu\text{g}/\text{mL}$) dissolved in $\text{H}_2\text{O}/\text{DMSO}$ (9/1, v/v). After incubation for 1 h at 37 °C, the absorbance of the hydroxylated salicylate complex was measured at 562 nm. Ascorbic acid and quercetin were used as positive controls. The scavenging activity of hydroxyl radical effect was calculated as follows: $[1 - (\text{A}_1 - \text{A}_2)/\text{A}_0] \times 100$, where A_0 is absorbance of the control (without sample), A_1

is absorbance in the presence of the sample and A_2 is absorbance without sodium salicylate. All the tests were conducted in triplicate and IC_{50} was determined by interpolation of concentration % inhibition curve obtained by MSExcel based program.

4.7.3. Power cupric ion reducing (CUPRAC)

Extracts, fractions and compounds **1-12** were tested for their power cupric ion reducing. The cupric ion reducing activity (CUPRAC) was determined according to a literature method (Ceylan et al., 2016) with a few modifications. Samples were prepared at concentrations of 572, 286, 143, 71.5, 35.75, 17.87 and 8.94 $\mu\text{g/mL}$ and dissolved in $\text{H}_2\text{O/DMSO}$ (9/1, v/v). 45 μL of each concentration were added to premixed reaction mixture containing CuCl_2 (90 μL , 10 mM), neocuproine freshly prepared (90 μL , 7.5 mM, dissolved in distilled water and ethanol in proportion 8/2, v/v) and NH_4Ac buffer (90 μL , 1M, pH 7.0). Similarly, a blank was prepared by adding sample solution (45 μL) to premixed reaction mixture (270 μL) without CuCl_2 . The reaction proceeded for 30 min at room temperature on a 96-well microplate and the absorbance was then read at 450 nm. Ascorbic acid, quercetin and trolox were used as positive controls. The power cupric ion reducing was calculated as follows: $[1 - A_0 / (A_1 - A_2)] \times 100$, where A_0 is absorbance of the control (without sample), A_1 is absorbance in the presence of the sample and A_2 is absorbance of the blank. All the tests were conducted in triplicate and IC_{50} were determined by interpolation of concentration % inhibition curve obtained by MSExcel based program.

4.8. Tyrosinase enzyme assay

Extracts, fractions and compounds **2, 4-6, 11** and **13** were tested for their ability to inhibit tyrosinase. The tyrosinase inhibitory activity was determined according to the method described previously (Lehbili et al., 2018) with a few modifications. Briefly, L-DOPA was used as the substrate in this experiment. Samples were prepared at concentrations of 1330, 665, 332.5, 166.25 and 83.12 $\mu\text{g/mL}$ and dissolved in phosphate buffer solution (PBS, 20 mM, pH 6.8) and DMSO in proportion 9/1 (v/v). 100 μL of each concentration were added to a 96-well microplate and then 100 μL of 135 U/mL fungal tyrosinase in PBS were added. After pre-incubation at room temperature for 10 min in the dark, 100 μL of L-DOPA (0.5 mM in PBS) were added. The reaction mixture was incubated for another 5 min at room temperature. The amount of dopachrome in the mixture was determined by the measurement of the absorbance of each well at 475 nm. Kojic acid was used as a positive control. The

inhibitory percentage of tyrosinase was calculated according to the following equation: % inhibition = $\{[(A - B) - (C - D)]/(A - B)\} \times 100$, where A is absorbance without sample, B is absorbance without sample and tyrosinase, C is absorbance with sample, and D is absorbance with sample and without tyrosinase. All the tests were conducted in triplicate. IC₅₀ were determined by interpolation of concentration % inhibition curve obtained by MSEXcel based program.

4.9. Elastase enzyme assay

Extracts, fractions and compounds **2-8** and **11-13** were tested for their ability to inhibit elastase. Elastase inhibition measurement was carried out using Human Leukocyte Elastase (HLE) (Merck Biosciences). Tests were performed in pre-coated 96-well microplates with 1% Serum Albumin Bovine. HLE (0.8 μ M) was incubated for 1 h at 27°C in Tris buffer (50 mM Tris-HCl pH 7.5 containing 500 mM NaCl) containing 0.1 to 1000 μ g/mL of tested sample. Sample solvent was used as a control. The assay was initiated by adding HLE fluorogenic substrate MeOSuc-Ala-Ala-Pro-Val-AMC ($\lambda_{exc} = 380$ nm/ $\lambda_{em} = 460$ nm) at a final concentration of 80 μ M. The rate of each substrate cleavage was measured in triplicate for each concentration examined, using an Infinite F200 PRO spectrofluorimeter (Tecan, Lyon, France) with one measure per minute for 60 min. HLE activity was calculated according to the following equation: % HLE activity = (Slope_{sample} x 100)/Slope_{control}, where slope_{sample} and slope_{control} are the slope of the fluorescence values as a function of time. Non-linear regression analysis with Graphpad software (La Jolla, USA) allowed us to calculate the IC₅₀.

Conflict of interest

The authors declare no conflict of interest.

Acknowledgements

The authors are grateful to ICMR and MEDyC laboratories (University Reims Champagne-Ardenne) for having allowed Mrs. Marie Schmitt to be able to perform all the necessary manipulations for the realization of this publication, as well as Grand Est region in France and EU-program FEDER to the PIAneT CPER project for financial support.
